

## CSC 572 ASSIGNMENT

Name: Onasoga Oluwapelumi Idris

Matric no: 214909

### Documentation of Code Setup and Output of Running Neural Network on the Mnist Dataset

#### Introduction

This dcoumentation describes the format and the output of the major.py script, which is used to train a neural network for the MNIST dataset through the use of the network2 module in the src package.

#### Imported Modules

The following modules are utilized in the main.py script:

**Argparse:** a built-in Python module for attribute value support of command-line arguments.

**Mnistloader:** A custom module within the src directory that loads the MNIST dataset.

#### Code Structure

The script sets up a main function, with an argument datasetpath, that refers to the position of the MNIST dataset. Within this function:

1. The MNIST dataset is loaded using mnistloader.loaddatawrapper.
2. A neural network with three layers (784, 30, 10) is created with the network2.Network class and cross-entropy as the cost function.
3. The network weights are initialized through the largeweightinitializer method.
4. Training is conducted using stochastic gradient descent (SGD) with a learning rate of 0.5, a regularization parameter of 0.1, and curve monitoring in terms of evaluation accuracy, the cost of evaluation, training accuracy, and training cost.

#### Output

The script, run during the training process, provides the main statistics, such as accuracy and cost.

#### Observation

1. **Training Cost and Evaluation Cost Trends** : The training cost started at 0.6189 and decreased slowly, reaching 0.2308 by epoch 29. Also, the evaluation cost followed a similar pattern, reducing from 0.7226 to 0.5476.  
The decrease in the costs shows that the model successfully minimized errors and learned meaningful patterns from the data.
2. **Accuracy Improvement** : The training accuracy improved from 90.88% (45441/50000) to 97.40% (48698/50000), while the evaluation accuracy increased from 90.60% (9060/10000) to 94.63% (9463/10000). This consistent improvement shows that the model is effectively learning and generalizing.

Note:  $\text{Accuracy} = (\text{Prediction} / \text{Total sample}) \times 100$

3. **Convergence Point and Overfitting Detection** : At epoch 17, the training accuracy had reached 97.02% (48510/ 50000), and evaluation accuracy hit 94.88% ( 9488 / 10000), showing the model was reaching peak performance.

After epoch 25, accuracy improvements became minimal, which shows that the model had learned most of what it could from the data. A slight increase in evaluation cost in later epochs suggests minor overfitting, where the model starts fitting too closely to the training data, slightly reducing generalization ability.
